

# Forecasting infectious-disease outbreaks

## The role of generation intervals

Jonathan Dushoff, McMaster University

U. Chicago, Oct 2018

# Outline

## Overview

### Model framework

- Compartmental models

### The $r\mathcal{R}$ relationship

- Generation intervals

### Generations through time

### Other kinds of generation interval

### Speed and strength

# Problem

- ▶ I am fundamentally a math person . . .

What is the pattern of Pythagorean triples of integers  
 $a^2 + b^2 = c^2$ ?

Divide a square and a circle each into two complementary subsets that are pairwise similar

How many at-bats does it take to get a given batting average?

# Problem

- ▶ I am fundamentally a math person
  - ▶ but I want to do work that is relevant to people

# Solution

- ▶ Dynamical modeling is fun and useful

# Dynamical modeling connects scales

Measles reports from England and Wales

- ▶ Start with rules about how things change in short time steps
  - ▶ Usually based on *individuals*
- ▶ Calculate results over longer time periods
  - ▶ Usually about *populations*

# Fun and useful!

# New problem

- ▶ There is (or was a gulf) between dynamical and statistical modeling
  - ▶ Dynamics are needed to incorporate mechanism
  - ▶ Statistics are needed to incorporate uncertainty

Speed and strength

# Compartmental models

Divide people into categories:

- ▶ Susceptible  $\rightarrow$  Infectious  $\rightarrow$  Recovered
- ▶ Individuals recover independently
- ▶ Individuals are infected by infectious people

# Differential equation implementation

# Individual-based implementation

# Lessons

- ▶ Tendency to oscillate
- ▶ Thresholds
- ▶ Exponential growth

# Big $\mathcal{R}$

- ▶  $\mathcal{R}$  is the number of people who would be infected by an infectious individual *in a fully susceptible population*.
- ▶  $\mathcal{R} = \beta/\gamma = \beta D = (cp)D$ 
  - ▶  $c$ : Contact Rate
  - ▶  $p$ : Probability of transmission (infectivity)
  - ▶  $D$ : Average duration of infection
- ▶ A disease can invade a population if and only if  $\mathcal{R} > 1$ .
- ▶ Often focus on initial period (may also say  $\mathcal{R}_0$ )

Big  $\mathcal{R}$

# Homogeneous endemic curve

- ▶ Threshold value
- ▶ Sharp response to changes in factors underlying transmission
- ▶ Works – sometimes
  - ▶ Sometimes predicts unrealistic sensitivity

# Yellow fever in Panama

# Exponential growth

- ▶ Diseases have a tendency to grow exponentially at first
  - ▶ I infect three people, they each infect 3 people ...
  - ▶ How fast does disease grow?
  - ▶ How quickly do we need to respond?

## little $r$

- ▶ We measure epidemic *speed* using little  $r$ :
  - ▶ *Units*: [1/time]
  - ▶ Disease increases like  $e^{rt}$
- ▶ Time scale is  $C = 1/r$ 
  - ▶ Ebola,  $C \approx 1\text{month}$
  - ▶ HIV in SSA,  $C \approx 18\text{month}$
- ▶ Often focus on initial period (may also say  $r_0$ )

little  $r$

# Limitations

- ▶ Many conclusions from this framework make strong assumptions:
  - ▶ **Spatial homogeneity:** everywhere is the same
  - ▶ **Individual homogeneity:** everyone is the same
    - ▶ and everyone is everywhere
  - ▶ **Temporal homogeneity:**
    - ▶ It doesn't matter how long I've been infected, I'm either infected or not

Other kinds of generation interval

Speed and strength

# The $r\mathcal{R}$ relationship

- ▶ We're very interested in the relationship between little  $r$  and  $\mathcal{R}$ .
- ▶ We might have good estimates of  $r$  only
  - ▶ e.g., West African Ebola outbreak, HIV in Africa
- ▶ Or we might have good estimates of  $\mathcal{R}$  only
  - ▶ Measles, influenza

# Example: Post-death transmission and safe burial

- ▶ How much Ebola spread occurs before vs. after death
- ▶ Highly context dependent
  - ▶ Funeral practices, disease knowledge
- ▶ *Weitz and Dushoff Scientific Reports 5:8751.*

# Standard disease model

## Add a latent period

- (i.e., a lag between infection and infectiousness)

## Add post-death transmission

## Add post-death transmission

# What happens if we account for burial transmission?

- ▶ We've made the disease transmitting process slower, so obviously Ebola is *less* dangerous than we thought
- ▶ We've added another source of transmission, so obviously Ebola is *more* dangerous than we thought
- ▶ What we learn depends on what we know!

# What do we know?

# Outline

Overview

Model framework

Compartmental models

The  $r\mathcal{R}$  relationship

Generation intervals

Generations through time

Other kinds of generation interval

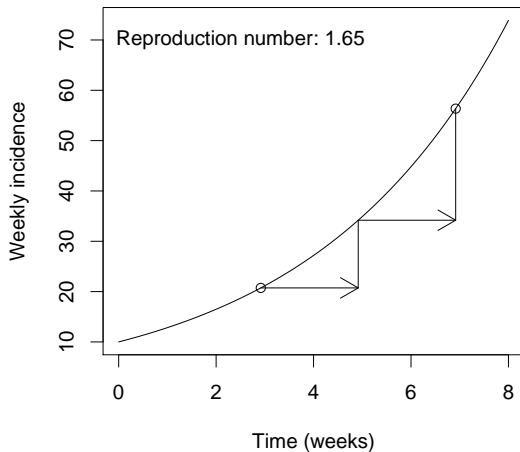

Speed and strength

# Generation intervals

- ▶ The generation distribution measures the time between generations of the disease
  - ▶ Interval between “index” infection and resulting infection
- ▶ Generation intervals provide the link between  $\mathcal{R}$  and  $r$

# Generations and $\mathcal{R}$

# Generations and $\mathcal{R}$

# Generations and $\mathcal{R}$

# Conditional effect of generation time

- ▶ *Given* the reproductive number  $\mathcal{R}$ 
  - ▶ faster generation time  $G$  means higher  $r$
  - ▶ More danger
- ▶ *Given*  $r$ 
  - ▶ faster generation time  $G$  means *smaller*  $\mathcal{R}$
  - ▶ Less danger

# Linking framework

- ▶ Epidemic speed ( $r$ ) is a *product*:
  - ▶ (something to do with) generation speed
  - ▶  $\times$  (something to do with) epidemic strength
- ▶ Epidemic strength (related to  $\mathcal{R}$ ) is therefore a *quotient*
  - ▶ Epidemic speed
  - ▶  $\div$  (something to do with) generation speed

# Filtered means

- ▶ There is a sensible way to define an “effective” generation time
- ▶ Preserve the exponential growth equation

$$\mathcal{R} = \exp(r\hat{G})$$

- ▶  $\hat{G}$  is a “filtered mean” of the distribution  $g$ :

$$\exp(-r\hat{G}) = \langle \exp(-r\tau) \rangle_g.$$

,

- ▶ This is cool, but not easy to interpret (our estimates about the generation time change when  $r$  changes)

# Approximations

**Approximate generation intervals**

# Moment approximation

**Approximate generation intervals**

# Moment approximation

**Approximate generation intervals**

# Moment approximation

**Approximate generation intervals**

# Compound-interest interpretation

- ▶ Define  $\mathcal{R} \approx (1 + r\kappa\bar{G})^{1/\kappa} \equiv X(r\bar{G}; 1/\kappa)$
- ▶  $X$  is the compound-interest approximation to the exponential
  - ▶ Linear when  $\kappa = 1$  (i.e., when  $g$  is exponential)
  - ▶ Approaches exponential as  $\kappa \rightarrow 0$

# Qualitative response

- ▶ For a given value of  $\bar{G}$ , smaller values of  $\kappa$  mean:
  - ▶ less variation in generation interval
  - ▶ less compounding of growth
  - ▶ greater  $\mathcal{R}$  required for a given  $r$

# Intuition

- ▶ Longer generation times mean less speed
  - ▶  $\implies$  more strength, when speed is fixed
- ▶ What about more variation?
  - ▶ More action (both before and after the mean time)
  - ▶ But what happens early is more important in a growing system
- ▶ More variation means more speed
  - ▶  $\implies$  less strength, when speed is fixed

# How well do approximations work

- ▶ Simulate realistic generation intervals for various diseases
- ▶ Compare approximate  $r\mathcal{R}$  relationship with known exact relationship
  - ▶ Known because we are testing ourselves with simulated data

# Ebola distribution

**Lognormal SEIR**

**Single-gamma approximation**

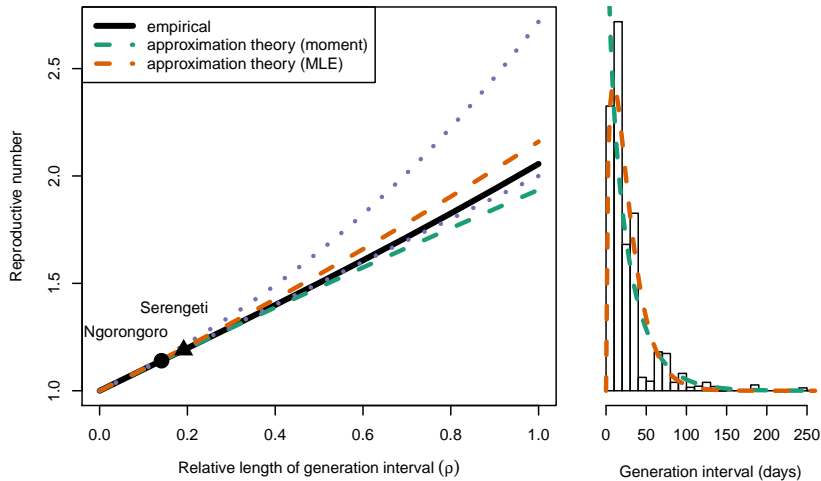

# Ebola curve

# Measles curve

# Rabies curve

# Generation intervals

- ▶ Sort of the poor relations of disease-modeling world
- ▶ Ad hoc methods
- ▶ Error often not propagated

# Summary

- ▶ Generation intervals are the missing link between  $r$  and  $\mathcal{R}$
- ▶ We need better methods for estimating them, and propagating uncertainty to other parts of the model
- ▶ Filtered means may help with intuition
- ▶ For many practical applications:
  - ▶ Estimating the mean generation interval is not enough
  - ▶ But estimating the mean and CV may be enough
  - ▶ A good basis for understanding and propagating uncertainty

# Outline

Model framework

Compartmental models

The  $r\mathcal{R}$  relationship

Generation intervals

Generations through time

Other kinds of generation interval

Speed and strength

# Generations through time

- ▶ Generation intervals can be estimated by:
  - ▶ Observing patients:
    - ▶ How long does it take to become infectious?
    - ▶ How long does it take to recover?
    - ▶ What is the time profile of infectiousness/activity?
  - ▶ Contact tracing
    - ▶ Who (probably) infected whom?
    - ▶ When did each become infected?
    - ▶ — or ill (serial interval)?

# Which is the real interval?

- ▶ Contact-tracing intervals look systematically different, depending on when you observe them.
- ▶ Observed in:
  - ▶ Real data, detailed simulations, simple model
- ▶ Also differ from intrinsic (infector centered) estimates

# Types of interval

- ▶ Define:
  - ▶ *Intrinsic interval*: How infectious is a patient at time  $\tau$  after infection?
  - ▶ *Forward interval*: When will the people infected today infect others?
  - ▶ *Backward interval*: When did the people who infected people today themselves become infected?
  - ▶ *Censored interval*: What do all the intervals observed up until a particular time look like?
    - ▶ Like backward intervals, if it's early in the epidemic

# Growing epidemics

- ▶ Generation intervals look *shorter* at the beginning of an epidemic
  - ▶ A disproportionate number of people are infectious right now
  - ▶ They haven't finished all of their transmitting
  - ▶ We are biased towards observing faster events

# What changes backward intervals?

- ▶ Who is likely to infect me depends on:
  - ▶ How infectious they are (intrinsic GI)
  - ▶ How many of them there are (changes in disease incidence)

# Backward intervals

*Champredon and Dushoff, 2015. DOI:10.1098/rspb.2015.2026*

# What changes forward intervals?

- ▶ Who I am likely to infect depends on:
  - ▶ How infectious I am (intrinsic GI)
  - ▶ How many of them there are (changes in numbers of susceptibles)

# Forward intervals

*Champredon and Dushoff, 2015. DOI:10.1098/rspb.2015.2026*

# Conclusion

- ▶ Backward intervals change if the number of infectious individuals is changing as you look back
- ▶ Forward intervals change if the number of *susceptible* individuals is changing as you look forward
- ▶ Lack of care in defining generation intervals can lead to bias
  - ▶ In particular, censored intervals look too short, lead to underestimates of  $\mathcal{R}$ .

Generation intervals

Generations through time

Other kinds of generation interval

Speed and strength

# Generations in space

- How do local interactions affect realized generation intervals?

 Individual

# Surprising results

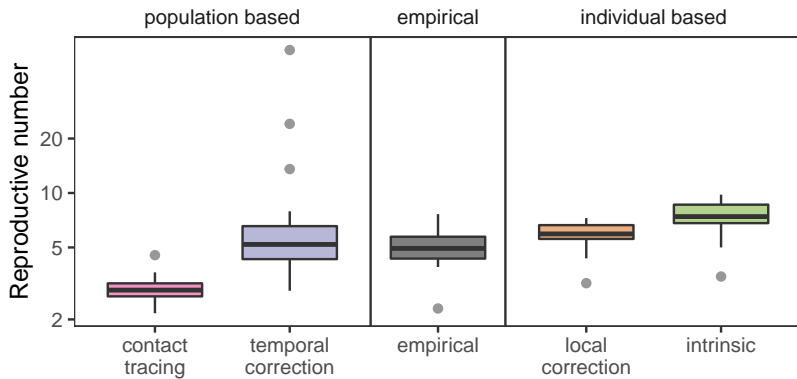

- ▶  $\mathcal{R}$  on networks generally *smaller* than values estimated using  $r$ .
  - ▶ Because people don't question the intrinsic generation interval
  - ▶ Local interactions
    - ▶  $\implies$  wasted contacts
    - ▶  $\implies$  shorter generation intervals
    - ▶  $\implies$  smaller estimates of  $\mathcal{R}$ .

# Observed and estimated intervals

# Outbreak estimation

# Serial intervals

- ▶ Do serial intervals and generation intervals have the same distribution?
- ▶ It seems that they should: they describe generations of the same process
- ▶ In fact, they don't
  - ▶ Serial intervals can even be negative!
  - ▶ You might report to the clinic with flu before me, even though I infected you

# Rabies

- ▶ If symptoms always start *before* infectiousness happens, then serial interval should equal generation interval:
  - ▶ incubation time + extra latent time + waiting time
  - ▶ extra latent time + waiting time + incubation time

Repeated biter incubation period

Speed and strength

# Can treatment stop the HIV epidemic?

- ▶ Modern treatments are well tolerated and highly effective
- ▶ Virus is undetectable, and transmission is negligible
- ▶ Can active testing and treatment stop the epidemic?

# Are HIV generations fast or slow?

- ▶ Fast generations mean:
  - ▶ Testing and treating will help less
  - ▶ *but* lower epidemic strength

# Eaton and Hallett

- ▶ Predicted effectiveness of test and treat intervention minimally sensitive to proportion of early transmission
- ▶ Fast transmission:
  - ▶ low proportion prevented, but low  $\mathcal{R}$  estimate
- ▶ Slow transmission:
  - ▶ high proportion prevented, but high  $\mathcal{R}$  estimate
- ▶ *Eaton JW, Hallett TB. Proc Natl Acad Sci U S A. 2014 Nov 11;111(45):16202-7.*

# Epidemic strength

►  $\mathcal{R}$ , the epidemic strength, is the area under the curve.

# Strength of intervention

... by what factor do I need to reduce this curve to eliminate the epidemic?

# Different interventions

# Different interventions

# Epidemic speed

►  $r$ , the epidemic speed, is the “discount” rate required to balance the tendency to grow

# Epidemic speed

►  $k(\tau) = \exp(r\tau)b(\tau)$ ,  
where  $b(\tau)$  is the initial  
backward generation  
interval

# Speed of intervention

... how *quickly* do I need to reduce this curve to eliminate the epidemic?

# Different interventions

Sometimes it's easier to estimate strength, sometimes speed

# The strength paradigm

- ▶  $\mathcal{R} > 1$  is a threshold
- ▶ If we can reduce transmission by a constant *factor* of  $\theta > \mathcal{R}$ , disease can be controlled
- ▶ In general, we can define  $\theta$  as a (harmonic) mean of the reduction factor over the course of an infection
  - ▶ weighted by the *intrinsic* generation interval
- ▶ Epidemic is controlled if  $\theta > \mathcal{R}$

# The speed paradigm

- ▶  $r > 0$  is a threshold
- ▶ If we can reduce transmission at a constant *hazard rate* of  $\phi > r$ , disease can be controlled
- ▶ In general, we can define  $\phi$  as a (very weird) mean of the reduction factor over the course of an infection
  - ▶ weighted by the *backward* generation interval
- ▶ Epidemic is controlled if  $\phi > r$

# Measuring the intervention

# HIV

- ▶ The importance of transmission speed to HIV control is easier to understand using the speed paradigm
  - ▶ We know the speed of invasion
    - ▶  $\approx 0.7/\text{yr}$
    - ▶ Characteristic scale  $\approx 1.4\text{yr}$
  - ▶ And can hypothesize the speed of intervention
    - ▶ Or aim to go fast enough

# Paradigms are complementary

- ▶ HIV
  - ▶ Information and current intervention are both “speed-like”
- ▶ Measles
  - ▶ Information (long-term) is strength-like
  - ▶ Intervention (vaccine) also strength-like
- ▶ Ebola vaccination
  - ▶ Information is speed-like
  - ▶ Pre-emptive vaccination is strength-like

# Thanks

- ▶ Department
- ▶ Collaborators
- ▶ Funders: NSERC, CIHR

# Linking framework

- ▶ Epidemic speed ( $r$ ) is a *product*:
  - ▶ (something to do with) generation speed  $\times$
  - ▶ (something to do with) epidemic strength
- ▶ In particular:
  - ▶  $r \approx (1/\bar{G}) \times \ell(\mathcal{R}; \kappa_g)$
  - ▶  $\ell$  is the inverse of  $X$
